提要:鄂尔多斯盆地作为中国重要的多种能源共生的大型盆地, 发育了大量的砂岩型铀矿床。本次工作选择盆地东北部纳岭沟铀矿床作为研究对象, 在直罗组含矿段附近采取5个砂岩样品进行碎屑锆石U-Pb定年, 并针对含矿样品进行电子探针分析。该地区直罗组含矿段碎屑锆石U-Pb年龄集中分布于5个阶段:(2479±11) Ma~(2460±19) Ma、(2300~1950) Ma、(1896±21) Ma~(1820±32) Ma、(316~266) Ma及165 Ma。同时, 本文整理了鄂尔多斯盆地北部造山带内古老变质基底、孔兹岩带和晚古生代侵入岩时代, 并发现在直罗组内获得的碎屑锆石年龄与北部造山带内地质体所记录的年龄相一致。结合前人地球化学及古地理研究, 本次工作推断纳岭沟地区直罗组砂岩沉积物最终来自于鄂尔多斯盆地北部造山带。纳岭沟铀矿床内铀矿赋存形式主要为存在于碎屑颗粒内部、黏土矿物周边、黄铁矿周边和炭屑裂隙内部。结合野外地质体放射性异常测量, 本次工作认为铀源主要来自于沉积成岩阶段含铀碎屑颗粒的预富集和后期高放射性异常地质体通过含铀含氧水向盆地内部的迁移。

关 键 词:鄂尔多斯盆地; 直罗组; 碎屑锆石; U-Pb定年; 铀矿

Abstract: The Ordos Basin is an important large basin with multi-energy resources, around which a series of sandstone-type uranium deposits are developed. The Nalinggou uranium deposit located in the northeastern part was chosen as a study object. Five sandstone samples surrounding the ore-bearing segment in the Zhiluo Formation were selected to make detrital zircon U-Pb dating, while electron microprobe analysis was performed for some sandstone samples with uranium minerals. The ages are distributed as 5 major peaks: (2479±11) Ma–(2460±19) Ma, (2300–1950) Ma, (1896±21) Ma–(1820±32) Ma, (316–266) Ma and 165 Ma. The authors further arranged the age data of metamorphosed basement, khondalite belt and Late Paleozoic intrusions in the orogenic belt on the north margin of the Ordos Basin. These zones of detrital zircons ages are consistent with the ages of geological bodies in the orogenic belts on the northern margin of the Ordos Basin. Combined with the previous work about geochemistry and paleogeography, the authors hold that the provenance of sandstone of Zhiluo Formation in Nalinggou area was finally derived from the orogenic belt on the northern margin of the Ordos Basin. The uranium minerals are spread in and around the clastic grains, clay minerals, pyrites, and fractures in charcoal fragments. The radioactive anomaly measurement in the field work shows that the uranium source probably came from the pre-enrichment of clastic grains from the provenance at the diagenetic stage, and from the migration of the uranium- and oxygen-bearing water through later leaching of the highly radioactive bodies of the provenance.

Key words: Ordos Basin; Zhiluo Formation; detrital zircon; U-Pb dating; uranium deposit

1 引言

鄂尔多斯盆地作为中国重要的多种能源共生的大型盆地,蕴含了大量的煤、油、气及铀等重要能源(邓军等,2005a;刘池洋等,2006)。该盆地位于中亚多金属成矿带及欧亚铀成矿带的东部,受古亚洲洋闭合及印支运动、燕山运动的影响,盆地周缘造山带活动频繁,自古近纪河套凹陷发育以来,处于相对稳定状态。盆地边缘发育了大量的砂岩型铀矿床,如盆地东北部的大营—东胜铀矿床(刘汉彬等,2007)、西部的宁东铀矿床(郭庆银等,2010)及南部的黄陵—店头铀矿床(邢秀娟等,2008)等等。这些铀矿床的发现,为我们进一步研究砂岩型铀成矿作用提供了天然实验室。

针对砂岩型铀成矿作用,前人已经从沉积环境和沉积相(杨仁超等,2007)、铀矿产出的部位、形态及分布(肖新建等,2004)、铀的成矿期次与成矿年代学(夏毓亮等,2003)、黏土矿物特征(杨晓勇等,2009)、赋矿砂岩的成岩作用及地球化学特征(罗静兰等,2005;张天福等,2016)、铀成矿作用与流体和有机质(孙晔等,2016)等方面进行了研究,并获得

了一批重要成果与认识。本文将通过对鄂尔多斯盆地东北部纳岭沟铀矿床含矿段附近层位砂岩内碎屑锆石进行U-Pb定年,加以对鄂尔多斯盆地北部出露岩石单元时代的分析,讨论纳岭沟铀矿床的物源问题,并剖析该地区含矿段铀矿物赋存形式,进一步研究该地区的铀源和铀成矿特征。

2 地质背景

鄂尔多斯盆地位于中亚造山带东段南缘,华北克拉通西部。其周缘分别为阴山—燕山造山带、吕梁山—太行山造山带及秦岭—大别造山带,为一大型陆相盆地。

2.1 区域地质背景

鄂尔多斯盆地以太古宇变质岩及古元古界海相沉积岩为基底,以古生界及中生界为盖层的大型陆相沉积盆地。变质基底受多期构造运动影响,形成纵横交错的断裂网(邓军等,2005b;Li et al., 2010; Wang et al., 2015)。盆地盖层在古生代为华北陆缘海—滨浅海盆地,接受了下古生界碳酸盐岩和上古生界海陆交互沉积。在晚三叠世—早白垩世,其为残存克拉通盆地,接受了大量河湖相及山前堆

积。晚白垩世以来,盆地整体受构造抬升剥蚀影响,普遍缺失晚白垩世以来的沉积。在新生界,古气候由湿热转向干旱,构造由沉降转为隆升,并在盆地周缘发育一系列断陷盆地(朱红涛,2005)。

鄂尔多斯盆地以稳定克拉通岩石圈为代表,盆地内部缺乏岩浆活动,仅在盆地东部出露有紫金山碱性侵入岩,在北缘白垩纪地层内发育一层玄武岩(肖媛媛等,2007;邹和平等,2008)。此外,王锡勇等(2010)指出在东部边缘有金伯利岩分布。

受多期构造运动影响,鄂尔多斯盆地西北部及北部出露大量的孔兹岩带,且周缘发育黄河坳陷、沁水盆地及渭河盆地等(图1)。根据现今鄂尔多斯盆地的构造形态、基底性质及构造特征,其可划分

为6个一级构造单元:伊盟隆起、西缘冲断带、天环坳陷、伊陕斜坡、晋西挠褶带和渭北隆起(图1)。

2.2 纳岭沟地区地质背景

本次研究区(纳岭沟铀矿区)位于鄂尔多斯盆地东北部,伊盟隆起东北缘微扬起端北翼,北部以河套坳陷为隔与阴山造山带(乌拉山、大青山)毗邻,东部毗邻吕梁—太行山造山带,向南为伊陕斜坡,转换为宽缓斜坡带(图1)。

该地区出露的地层主要为早白垩世东胜组,在东北部盆缘出露寒武—奥陶纪、二叠—侏罗纪沉积单元,形成该地区环形出露的构造格局(图2,图3)。地层整体角度宽缓,向南西倾,倾角1~10°。自三叠纪以来,该地区主要发育:三叠纪刘家沟组、和

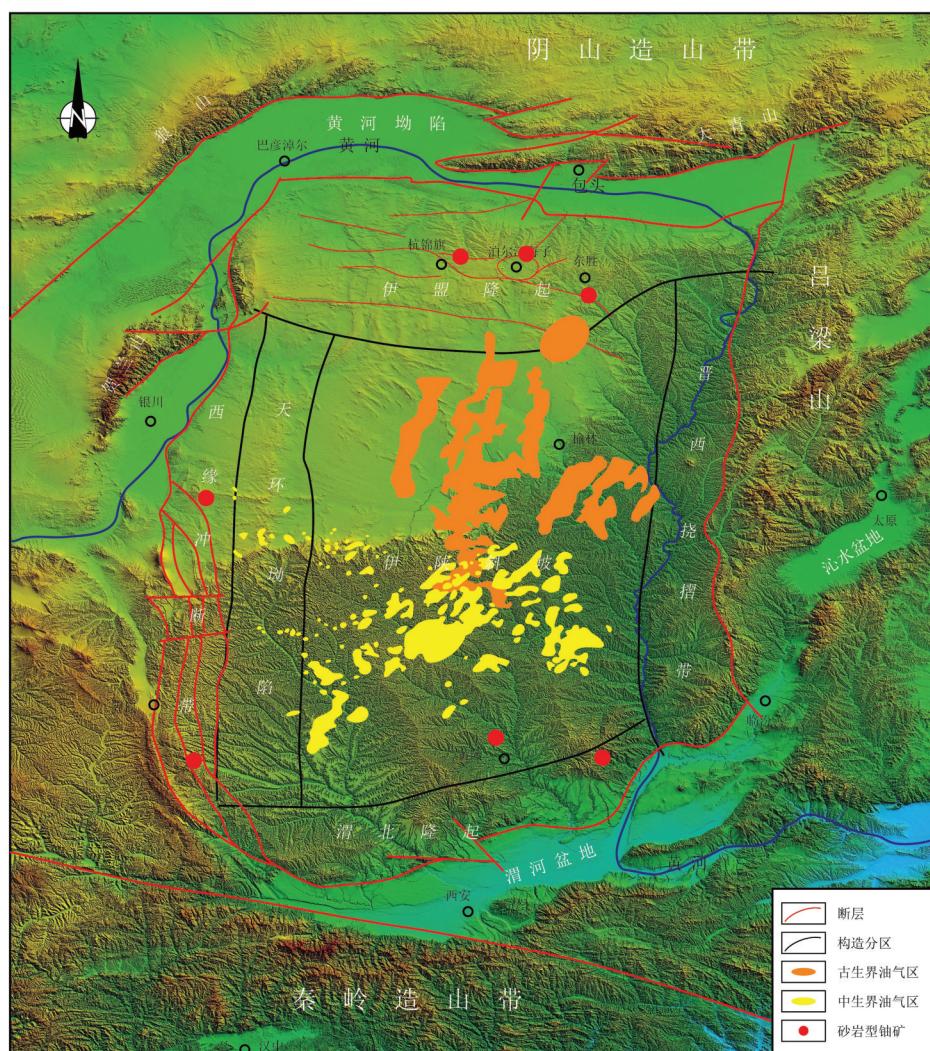

图1 鄂尔多斯盆地DEM图及构造区域划分(参考于王建民等,2013)

Fig. 1 DEM map of the Ordos Basin with regional tectonic division(modified from Wang et al., 2013)

尚沟组、纸坊组和延长组;侏罗系富县组、延安组、直罗组、安定组及芬芳河组;早白垩世伊金霍洛组和东胜组(图4)。受印支运动Ⅰ幕影响,延长组与纸坊组为角度不整合接触。侏罗系为该地区主要的铀含矿层,受印支运动Ⅱ幕影响,与下伏三叠纪地层角度不整合接触,受燕山运动A幕影响,与上覆白垩系以角度不整合接触(图5a,b)。白垩系为

该地区出露的主要地层,受燕山运动B幕及喜山运动影响,后期遭受大规模的抬升剥蚀。

中侏罗统直罗组为纳岭沟地区重要的含铀层,成南北向带状分布,与上下层位均有明显的沉积间断面(图6,图5b,c)。直罗组可以划分为上段和下段(上亚段、下亚段)(图6)。下段下亚段主要为辫状河-辫状河三角洲沉积相的中-粗砂岩,主要表现

为灰色、灰白色和灰绿色,局部地区底部可见砾岩层。下亚段为纳岭沟地区主要的含铀层,靠近延安组的层位发育大量的炭屑、黄铁矿及碳酸盐胶结。下段上亚段为低弯度曲流河沉积相的泥-沙-泥组合,以灰绿色中细砂岩夹泥岩为主,为该地区次要的含铀层位。直罗组上段主要为杂色砂岩夹泥岩,为干旱气候下河流及泛滥平原沉积体系,多表现为

灰绿色砂岩与红色泥岩互层发育(图5b)。

下侏罗统延安组主要为河湖相及沼泽相下沉积的灰色砂岩及黑色煤系(图6)。部分学者认为其顶部发育的一层白色砂岩为油气漂白带(吴柏林等,2015)或古风化壳(焦养泉等,2015)(图5c)。

该地区地层相对稳定,区域性构造相对不发育,主要表现为杭锦旗断裂带(Yang et al., 2013)。

纳岭沟地区遥感影像及DEM图像显示,该地区发育一环形构造带,并发育NW-SE向的东胜—石湾子断隆构造带及本害敖包—准格尔召断层(刘德长等,2006)。野外露头显示,该地区白垩纪地层内局部发育断裂构造(图5e,f)。岩心观察同样显示,在白垩系和侏罗系内常见断层发育,其中在侏罗系内部分正断层为早期逆断层的再活化(图5g,h,i)。

在纳岭沟北部地区杭锦旗黑石头沟,在下白垩统砂岩之上发育一层玄武岩,全岩Ar/Ar年龄为126 Ma,形成于早白垩世,与鄂尔多斯盆地东部紫金山岩

体(137~130 Ma)的年龄接近,反映了该地区在早白垩世发生了一次构造—岩浆—热事件(邹和平等,2008)。

3 碎屑锆石U-Pb定年

本次工作主要集中于鄂尔多斯盆地东北部纳岭沟地区,共采集4个含矿孔直罗组下段含矿段周缘层位砂岩样品,1个无矿孔含矿段相等层位砂岩样品(72111k14)。

3.1 测试方法

本次工作碎屑锆石筛选由廊坊市宇能岩石矿

(据核工业208地质队资料修改)

Fig.6 Comprehensive column of ore-bearing segment in the Nalinggou uranium orefield, northern part of the Ordos Basin (modified from Nuclear Industry Geological Team No.208)

物分选技术服务有限公司完成。锆石靶、CL图像及锆石U-Pb测试工作在天津地质调查中心实验测试

室完成。本次锆石U-Pb测试使用的仪器为具有New Wave UP-213激光剥蚀系统的Thermo Finnigan Element2(高分辨率电感耦合等离子体质谱仪),具体仪器参数请参照Chang et al.(2006)。

3.2 碎屑锆石 U-Pb 定年结果

锆石CL图像显示,除1672k11样品外,其余样品中碎屑锆石直径普遍小于150 μm (图7)。样品中较年轻锆石多呈棱角状,具有岩浆环带,无古老核的存在。古老锆石多呈棱角状、次圆状的扇形,部分可见古老的核,且环带不明显。1672k17样品采自于直罗组底部含砾砂岩之上的层位,其碎屑锆石多呈棱角状,且直径较大,可达200 μm 。此外,5个样品的测试锆石颗粒均大于80个。

2836k14 样品位位于矿区西部,其古老锆石主要峰值加权平均年龄为 (2466 ± 12) Ma 和 (1896 ± 21) Ma,且两者所占比例相当,次峰值区间为 2200~2100 Ma,其中最古老锆石年龄为 (2556 ± 13) Ma。年轻碎屑锆石年龄较少,且分布分散,无加权平均年龄,但发现一个中侏罗世年龄记录 (164 ± 2) Ma。

72111k17 样品位位于矿区的东部,为无矿孔样品,其古老锆石分布相对较分散,其主要峰值加权平均年龄为 (2476 ± 22) Ma 和 (1820 ± 32) Ma, 其中后者所占比例较大, 次峰值区间为 $(2300\sim2150)$ Ma, 最古老锆石年龄为 (2546 ± 17) Ma。其晚古生代年龄集中分布于 316 Ma 左右。

1672k11 样品位位于矿区西部,其古老锆石主要峰值加权平均年龄为 (2463 ± 13) Ma 和 (1856 ± 9) Ma, 次峰值区间为 $(2050\sim1950)$ Ma, 最古老锆石年龄为 (2666 ± 21) Ma。年轻碎屑锆石年龄相对其他样品较少,集中于晚古生代。

1262k15 样品位于矿区西部,其碎屑锆石年龄分布相对集中,古老锆石主要峰值加权平均年龄为 (2479 ± 11) Ma 和 (1843 ± 10) Ma, 次峰值区间为 $(2300\sim2100)$ Ma; 年轻锆石加权平均年龄为 (266.3 ± 2.9) Ma。其中最古老锆石年龄为 (2551 ± 21) Ma。该样品中同样具有中侏罗世碎屑锆石年龄记录,为 (164.5 ± 2) Ma。

3112k14 样品位于矿区的南部,采样深度较大,古老锆石主要峰值加权平均年龄为(2460±19) Ma 和(1846±10) Ma,次峰值区间为(2300~2200) Ma;年轻锆石谱和年龄为(285.4±3.9) Ma。其中最古老锆石

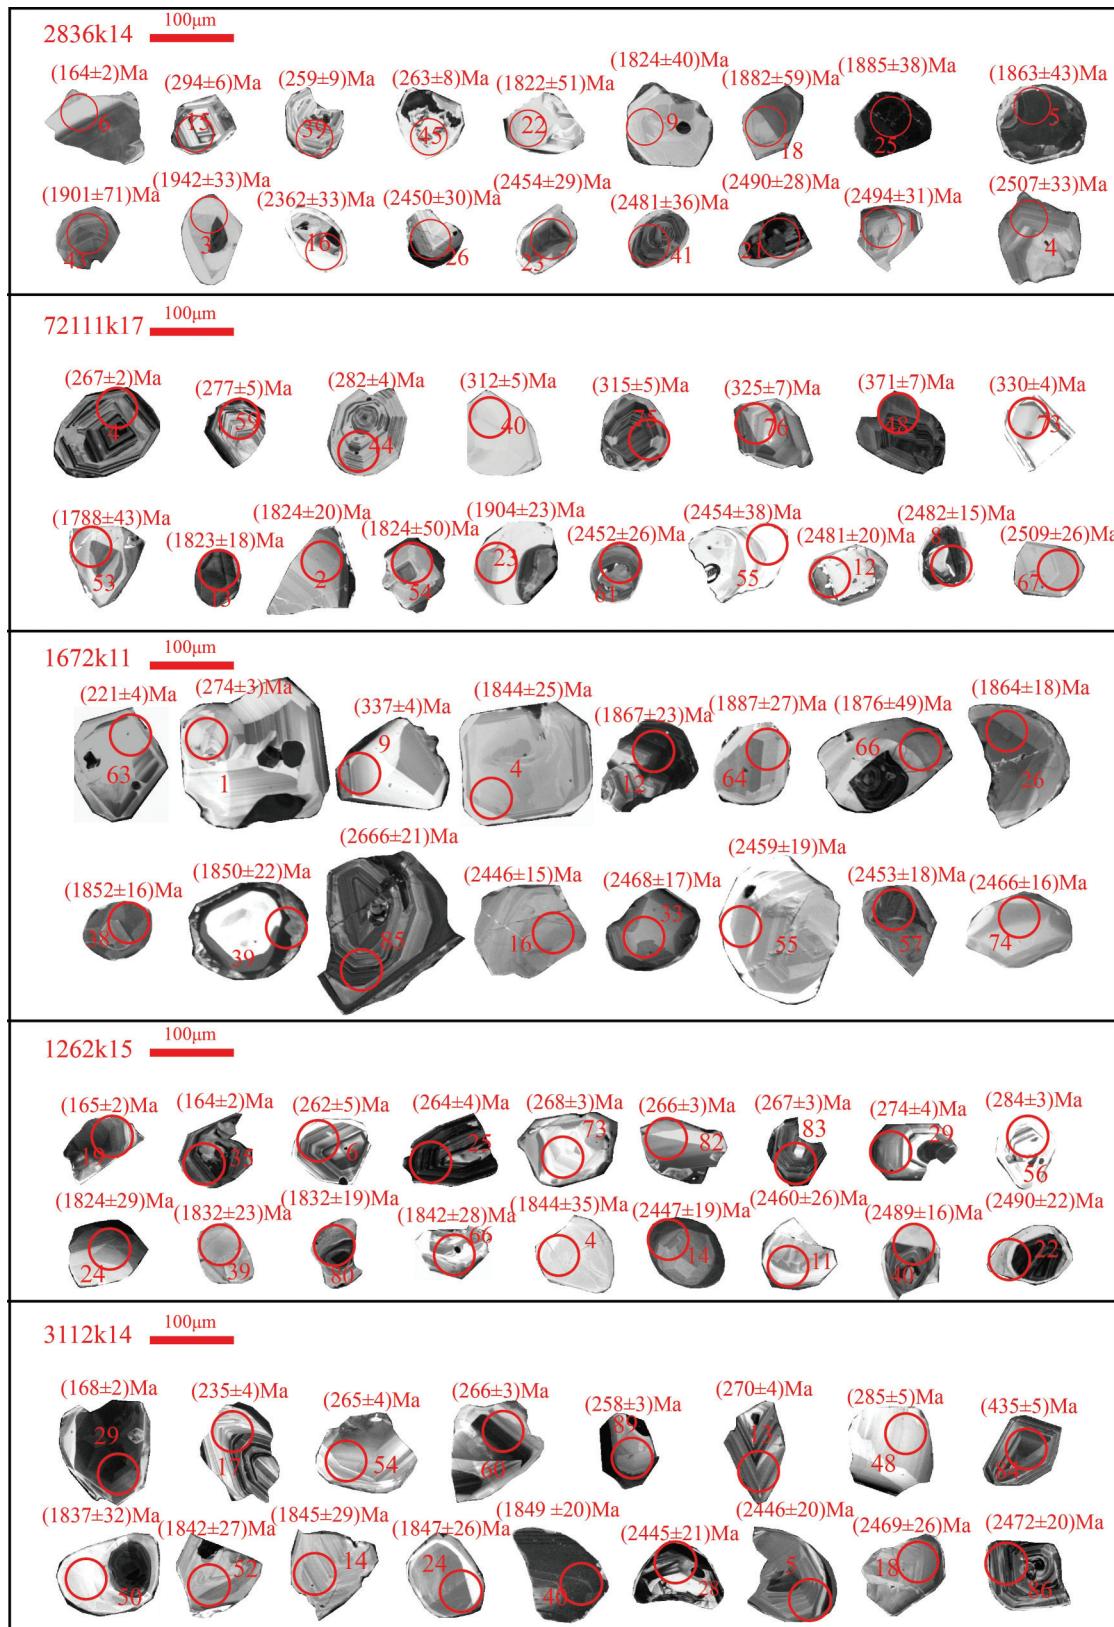

图7 纳岭沟铀矿区碎屑锆石CL图像
Fig.7 CL images of detrital zircons from Nalinggou uranium deposit

年龄为(2598±20) Ma。该样品中亦发现中侏罗世碎屑锆石。

在所有样品中,中侏罗世(168~164)Ma的碎屑锆石,呈不规则棱角状,具有弱的岩浆环带,Th/U为0.65~1.05,为岩浆成因锆石(图7,表1)。

综上所述,纳岭沟地区直罗组下段含矿层位周边砂岩内碎屑锆石年龄分布具有明显的一致性(图8,图9),集中分布于5个阶段:(2479±11) Ma~(2460±19) Ma、(2300~1950) Ma、(1896±21) Ma~1820±32) Ma、(316~266) Ma及165 Ma。该地区所发现的最古老碎屑锆石年龄为(2666±21) Ma,最年轻碎屑锆石年龄为(164±2) Ma。

4 讨 论

4.1 碎屑锆石U-Pb定年对物源区的示踪作用

鄂尔多斯盆地周缘出露大量的太古宙变质基底、孔兹岩带、元古宙沉积以及古生代和中生代侵入岩。自三叠纪以来,盆地北缘经历了印支运动、燕山运动和喜山运动,造成众多放射性异常地质体出露地表。由上文可知,盆地东北部直罗组内碎屑锆石年龄主要包括5个阶段:(2479±11) Ma~(2460 ± 19) Ma、(2300~1950) Ma、(1896 ± 21) Ma~(1820±32) Ma、(316~266) Ma及165 Ma,并与鄂尔多斯盆地北缘造山带出露的岩石单元具有很好的对应关系。

本次工作得到大量(2479±11) Ma~(2460±19) Ma碎屑锆石年龄,其中最古老碎屑锆石年龄为(2666±21) Ma。这与鄂尔多斯盆地北部出露的太古宙TTG岩系及一系列镁铁质、超镁铁质侵入岩的时代相一致(图2),指示在纳岭沟地区直罗组内获得的新太古代—古元古代古老碎屑锆石最终来自于鄂尔多斯盆地北部阴山造山带内古老的变质基底或其他捕获此类锆石的地质体。前人大量年代学研

究表明,鄂尔多斯盆地北缘造山带内出现大量的TTG岩系及一系列镁铁质、超镁铁质侵入岩,时代为(2.6~2.5) Ga(Zhao et al., 2005; Guan et al., 2002; Wan et al., 2013)。在内蒙古固阳地区和乌拉山—集宁地区,麻粒岩年龄为(2.65~2.35) Ga(张维杰等,2000;王惠初等,2001;吴昌华等,2006;刘建辉等,2013)。因此,本次纳岭沟地区直罗组含矿段具有与盆地北缘出露的变质岩系时代相一致的碎屑锆石年龄。直罗组内碎屑锆石年龄主要集中分布在(2300~1950) Ma、(1896±21) Ma~(1820±32) Ma;其中以后者为重要的峰值分布区间。这与鄂尔多斯盆地西部及北部出露的孔兹岩带内锆石的年龄记录相一致。前人研究表明孔兹岩系原岩沉积年龄为(2.3~1.9) Ga,并在(2.0~1.9) Ga发生重大变质事件(Xia et al., 2006; Wan et al., 2006)。同时该地区在1.92 Ga发生板片断离,形成大量的岩浆活动及镁铁质岩脉的大规模侵入,并在1.85 Ga左右发生华北克拉通东西陆块的碰撞拼贴(Yin et al., 2009)。这一碎屑锆石年龄分析结果与孔兹岩带地区的构造演化时间段相一致,进一步指示直罗组内该阶段碎屑锆石最终来源于盆地北缘孔兹岩带。

Zhang et al.(2012)在对华北克拉通北缘碱性杂岩体研究时,指出在华北克拉通北缘发育大规模(250~200) Ma的花岗质侵入体。同时,牛晓露等(2016)指出华北克拉通北缘包头东正长岩是华北克拉通北缘三叠纪碱性岩带最西端的岩体,年龄为(214.7±1.1) Ma。但本次工作中,直罗组内缺乏该阶段碎屑锆石年龄记录。

本次研究在多个样品中发现了中侏罗世碎屑锆石年龄,与直罗组沉积的时代基本一致(图7,图9,表1)。根据前人研究,在华北克拉通北部阴山—燕山造山带内发育大量侏罗系盆地,并分布一系列火山岩(Davis et al., 2001)。此外,赵宏刚(2005)在

Fig.9 Results of younger detrital zircon U-Pb dating

研究鄂尔多斯盆地构造演化与铀成矿关系时,指出鄂尔多斯盆地在中侏罗世直罗组时期经历了一次火山活动。针对本次工作获得的165 Ma左右的锆石年龄,本文推测其为阴山—燕山地区中生代侏罗纪火山活动的记录,但需进一步研究证实。

综上所述,本次工作在纳岭沟直罗组含矿段砂岩内获得的碎屑锆石年代学研究表明,碎屑锆石所记录的多阶段年龄均与鄂尔多斯盆地北缘出露的岩石单元的时代相一致。同时,碎屑锆石形态多呈棱角状,亦反映了近源搬运的特征。进一步结合前人对东胜地区直罗组砂岩地球化学特征及古地理研究成果(李宏涛等,2007;吴兆剑等,2013;王盟等,2013;焦养泉等,2015),本文认为直罗组含矿段砂岩的物质源区为北部的阴山造山带。

根据这些锆石年龄记录,并结合上述前人研究成果,本文认为纳岭沟直罗组碎屑锆石的年龄分布反映了北部造山带内地质体的时代分布。在(2479±11) Ma ~ (2460±19) Ma, 太古宙TTG岩系等变质基底发育。(2300~1950) Ma、(1896±21) Ma ~ (1820±32) Ma代表了孔兹岩系发育的时代,以及华北克拉通东西板块的碰撞拼贴的时间。(316~266) Ma指示该地区由于古亚洲洋闭合引起的大规模岩浆活动。碎屑锆石缺乏(250~200) Ma的记录,表明该时期地质体在中侏罗世未抬升至地表遭受剥蚀。至中侏罗世(165 Ma),阴山—燕山造山带普遍发育火山活动,并剥蚀搬运至盆地内部沉积。

此外,鄂尔多斯盆地北缘三叠纪以来构造变形以盆缘为主,在盆地内部构造变形较弱。印支运动的发育造成鄂尔多斯盆地北缘造山带物源区的形成,在盆地内部则发育含油、含煤等富有机质沉积体系,为后期铀的成矿富集提供大量的还原性介质。晚侏罗世燕山运动A幕的发育,造成鄂尔多斯盆地东部强烈抬升,东西两侧挤压变形,形成盆—山耦合体系。燕山运动B幕以后,鄂尔多斯盆地整体处于抬升剥蚀状态,保持了相对稳定的水动力条件及物源区来源,有利于含铀含氧水沿盆地边缘地层隆起端向下运移,与大量还原性介质接触,造成铀矿物的沉淀富集成矿。此外,区域应力场特征表明,鄂尔多斯盆地北缘遭受了长期的挤压变形(张岳桥等,2006),使该地区隆升剥蚀而成为鄂尔多斯盆地北缘主要的物源区。

4.2 铀矿物赋存形式及其对铀源的指示

本次工作通过对含矿砂岩电子探针研究表明,铀矿物的存在形式主要有几种:(1)存在于碎屑颗粒内部;(2)吸附于碎屑颗粒边缘黏土层周边;(3)存在于黄铁矿颗粒(包括不规则状黄铁矿、细脉状黄铁矿及草莓状黄铁矿)边缘;(4)少量存在于炭质条带裂隙内;(5)黏土矿化矿物周边(图10)。

在纳岭沟地区,部分钻孔内可见含铀碎屑颗粒的存在。这些碎屑颗粒普遍被一层黏土类矿物薄层包裹,避免了颗粒内部铀矿物受后期流体影响。由于纳岭沟地区含矿段砂岩内普遍发育黏土类矿物,具有较强的吸附能力,后期流体成因的铀矿物易在黏土矿物表面吸附富集。在纳岭沟直罗组下亚段普遍发育黄铁矿。大部分黄铁矿以不规则状存在,胶结早期碎屑颗粒或沿裂隙呈脉状发育。另一部分黄铁矿以细小的草莓状黄铁矿颗粒存在。由于黄铁矿的还原能力,可将含氧含铀流体中的铀元素在黄铁矿周边还原富集沉淀成矿。直罗组下段发育大量的炭屑,为铀矿物的氧化还原作用提供了很好的还原环境,由于炭屑本身的还原能力和吸附能力,在炭屑孔隙内发育铀矿物。早期解理发育的矿物,如云母类矿物,受后期流体等作用发生强烈的粘土化,但保留了早期矿物的形态。因黏土矿物强烈的吸附能力,易于铀富集成矿。

樊爱萍等(2007)指出东胜地区成岩序列为:玉髓→绿泥石薄膜(蒙脱石、伊/蒙混层和绿/蒙混层)→孔隙充填绿泥石、伊利石→泥晶方解石→长石溶蚀、自生高岭石、石英次生加大→亮晶方解石、黄铁矿、水化黑云母。这显示纳岭沟地区碎屑颗粒边缘普遍发育的黏土层为早期成岩阶段的产物。因此,直罗组内保存完好的含铀碎屑颗粒来自含铀地质体,并可作为纳岭沟地区后期铀成矿的铀源。

鄂尔多斯盆地北缘乌拉山地区野外放射性测量发现,该地区存在大量的放射性异常地质体,尤其以钾长花岗伟晶岩脉和石英岩脉为代表(图5d)。这与张复新等(2006)的研究成果相一致,在阴山褶皱系,表现为高钾异常带,U、Au等元素伴随钾、钠的活化分异而迁移富集。便携式 γ 能谱仪测试显示,出露的异常地质体以Th异常为主。但U-Th异常常伴生出现,且U的地球化学特征相对较活泼,易受地表水淋滤及氧化作用形成含铀含氧水而

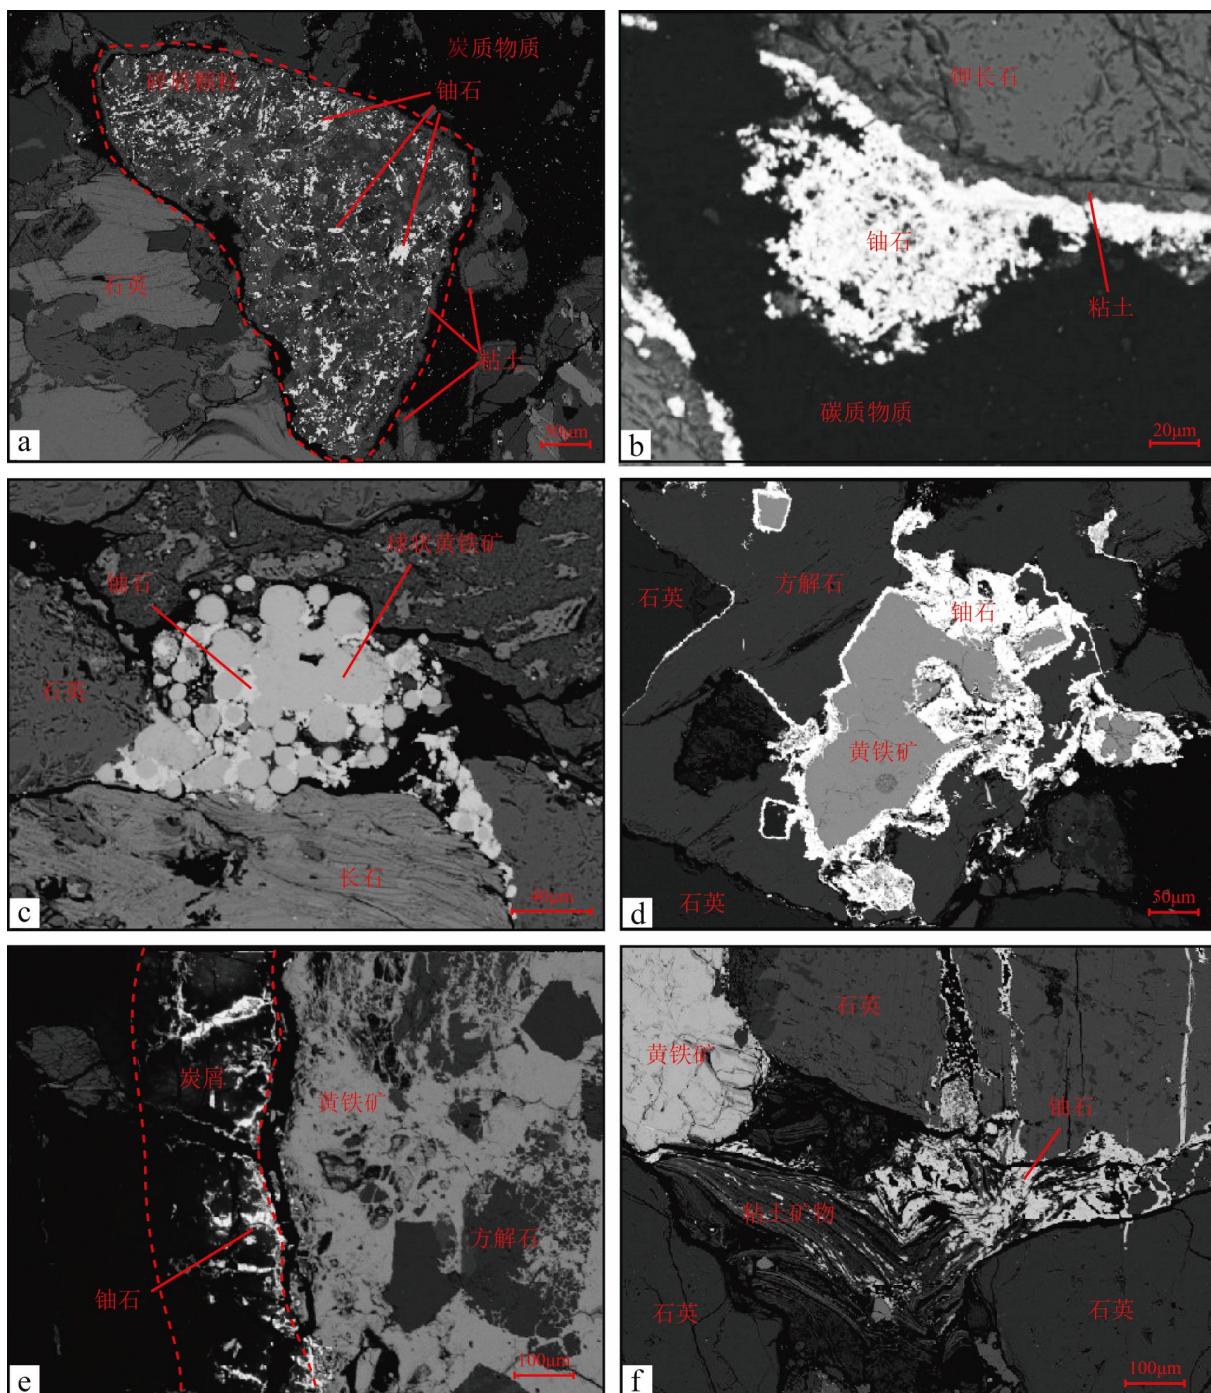

图 10 纳岭沟铀矿区铀矿物赋存形式

a—铀矿物存在与碎屑颗粒内部;b—铀矿物吸附于颗粒边缘的黏土层上;c—草莓状黄铁矿周边发育铀矿物;d—不规则黄铁矿周围发育铀矿物;e—炭质条带裂隙内发育铀矿物;f—黏土矿化颗粒周边及解理内发育铀矿物

Fig. 10 Uranium minerals of the Nalingou uranium orefield

a—Uranium minerals in the detrital grain; b—Uranium minerals absorbed to the clay layer around the grain; c—Uranium minerals developed surrounding the framboidal pyrite; d—Uranium minerals developed around the irregular pyrite; e—Uranium minerals developed in the fractures of carbon belts; f—Uranium minerals developed around the clay mineralized clastic grains and in their cleavages

流失,形成以Th异常为主的“氧化帽”。在乌拉山山前第四系堆积内,本次工作同样发现了相对较高的放射性异常。此外,前人已经指出乌拉山地区大桦背岩体的时代为330 Ma。且前文已经提到,纳岭沟含矿段直罗组砂岩内亦有该时期碎屑锆石记录。这表明,目前鄂尔多斯盆地北缘乌拉山地区出露的放射性异常地质体在中侏罗世可能已经局部出露地表遭受剥蚀,而可以作为纳岭沟地区铀成矿的铀源。因此,鄂尔多斯盆地北缘物源区放射性异常地质体,早期为直罗组提供了大量含铀矿物的碎屑颗粒,导致沉积层铀矿物的原始富集;后期物源区由于淋滤作用形成的大量含铀含氧水,沿盆缘剥露区及断层向下运移,经直罗组遇还原性介质发生氧化还原反应,在黏土矿物表面吸附富集成矿。

5 结 论

本次工作对纳岭沟地区直罗组含矿段附近砂岩碎屑锆石U-Pb年代学及含矿段砂岩电子探针的研究表明:

(1) 纳岭沟直罗组砂岩内碎屑锆石U-Pb年龄集中分布于5个阶段:(2479±11)Ma~(2460±19)Ma、(2300~1950)Ma、(1896±21)Ma~(1820±32)Ma、(316~266)Ma及165 Ma。其中,最古老碎屑锆石年龄为(2666±21)Ma,最年轻碎屑锆石年龄为(164±2)Ma。该年龄分布与鄂尔多斯盆地北部造山带内地质体内记录的时间相一致,进一步指示了纳岭沟地区直罗组砂岩物源区为鄂尔多斯盆地北部造山带。

(2) 纳岭沟铀矿床内铀矿物的赋存形式主要表现为碎屑颗粒内部、黏土矿物周边、黄铁矿周边和部分炭屑裂隙内。其中碎屑颗粒内部铀矿物的富集指示了该地区铀成矿的原始富集。

(3) 纳岭沟铀矿床的铀源主要来自于沉积成岩阶段盆地北部阴山造山带内含铀碎屑颗粒的富集和后期物源区高异常地质体通过含铀含氧水向盆地内部的迁移。

感谢:在锆石U-Pb测试和电子探针测试过程中得到了天津地质调查中心实验室肖志斌、张永清和郭虎的大力支持,在样品采集过程中得到了中国核工业二〇八大队的大力支持,在此一致表示感谢。同时感谢评审专家及编辑提出的宝贵意见。
